All types of glaucoma involve glaucomatous optic neuropathy. The key to detection and management of glaucoma is understanding how to examine the optic nerve head (ONH). This pictorial glossary addresses the following issues:

- how to examine the ONH
- normal characteristics of the ONH
- characteristics of a glaucomatous ONH
- how to tell if the glaucomatous optic neuropathy is getting worse
- ‘pitfalls and pearls’.

How to examine the ONH clinically

The ONH can be examined using a direct ophthalmoscope, an indirect ophthalmoscope, or using a posterior pole lens with a slit lamp. Many types of health professionals can assess the ONH accurately if they have appropriate training. The time available to view the ONH is often short as the examination is uncomfortable for the patient, so it is essential that the examiner has a strategy in mind to answer some key observations. Dilating the pupil facilitates examination of the ONH.

The examination is uncomfortable for the patient, so it is essential that the examiner has a strategy in mind to answer some key observations. Dilating the pupil facilitates the examination of the optic disc and provide quantitative measurements.

Characteristics of the normal ONH

The ONH or optic disc is a round/oval ‘plug-hole’, down which more than a million nerve fibres descend through a sieve-like sheet known as the lamina cribrosa. These fibres are then bundled together behind the eye as the optic nerve which continues towards the brain.

The retinal nerve fibres are spread unevenly across the surface of the retina in a thin layer which has a ‘feathery’ appearance. The sheer size of these dense packs of nerve fibres is best seen immediately above and below the disc. As the nerve fibres converge on the edge of the disc they pour over the scleral rim which borders the inner surface. These dense packing of nerve fibres just inside the scleral rim is visualised as the neuroretinal rim. The cup is the area central to the neuroretinal rim. The cup edge (where it meets the neuroretinal rim) is best seen by the bend in small and medium-sized blood vessels as they descend into the cup. The inferior rim is usually thicker than the superior rim, which is thicker than the nasal rim, and the temporal rim is the thinnest (this is known as the ‘TSNT’ rule).

Characteristics of a glaucomatous ONH

Glaucomatous optic neuropathy: generalised enlargement of cup

- generalised/focal enlargement of the cup
- disc haemorrhage (within 1 disc diameter of ONH)
- thinning of neuroretinal rim (usually at superior & inferior poles)
- asymmetry of cupping between patient’s eyes
- loss of nerve fibre layer
- parapapillary atrophy (more common in glaucomatous eyes).

Distinguishing a glaucomatous ONH from a normal ONH

Learn the features of a normal and a glaucomatous ONH (above).

Strategy:

1. Dilate pupils, if possible and safe to do so.
2. Identify disc edge and cup edge thereby identifying rim.
3. Does the rim thickness obey the ISNT rule?
4. Is there a haemorrhage?
5. Estimate vertical cup/disc ratio.

Further reading

‘Pitfalls and pearls’

The hallmark of glaucomatous optic neuropathy is excavation of the neuroretinal rim.

Advanced glaucomatous ONH can result in a pale optic disc but disc pallor should raise a suspicion of another cause such as optic atrophy.

A colour difference should not be used to distinguish the cup edge; change in direction of the blood vessels is a more reliable indicator.

The optic disc abnormality should correlate with the visual field defect. Where this is not the case, further investigations (e.g., CT/MRI scan) may be indicated.

The size of the cup always appears smaller when viewed monoscopically than in stereo.

A measurement of cup/disc ratio (CDR) alone is insufficient and may be misleading as small discs will have smaller cups and hence a smaller CDR.

An example of progression of glaucomatous optic neuropathy (left eye) over 7 years. Note the progressive thinning of the neuroretinal rim, in particular in the superonasal quadrant.

Instrument Advantages Disadvantages
Direct ophthalmoscope Portable; cheap; magnified view No stereo view
Indirect ophthalmoscope Portable; useful to examine children, may see through media opacity Limited magnification
Slit lamp + posterior pole lens Stereo view; high magnification and illumination Expensive; heavy

Glucomatous optic neuropathy: splinter haemorrhages

Glucomatous optic neuropathy: focal enlargement of cup (notch) and nerve fibre layer defect

6 Measure size of ONH. *
7 Examine the retinal nerve fibre layer (using green light). *
8 Draw an annotated diagram of the ONH. * May only be possible with slit lamp and posterior pole lens

Is the glaucomatous optic neuropathy getting worse/ progressing?

The appearance of any of the features of a glaucomatous ONH, or the exacerbation of these features compared to a previous record, is indicative of a progression/worsening of the disease. Disc haemorrhages may be present for two weeks to three months and are an important prognostic sign of progression. An accurate record requires careful observation and a detailed drawing, at the very least. Photographic documentation (preferably stereophotography) is highly recommended. Other imaging devices offer progression analyses, but these are not a surrogate for a detailed clinical examination. Progressive worsening of the visual fields should correlate with structural changes at the ONH.
